Chapter 2 Application Layer

James F. Kurose | Keith W. Ross COMPUTER A TOP-DOWN APPROACH P **Eighth Edition**

Computer Networking: A Top-Down Approach

8th edition n Jim Kurose, Keith Ross Pearson, 2020

Application Layer: Overview

- Principles of network applications
- Web and HTTP
- E-mail, SMTP, IMAP
- The Domain Name System DNS

- P2P applications
- video streaming and content distribution networks
- socket programming with UDP and TCP

DNS: Domain Name System

people: many identifiers:

SSN, name, passport #

Internet hosts, routers:

- IP address (32 bit) used for addressing datagrams
- "name", e.g., cs.umass.edu used by humans

Q: how to map between IP address and name, and vice versa?

Domain Name System (DNS):

- distributed database implemented in hierarchy of many name servers
- application-layer protocol: hosts, DNS servers communicate to resolve names (address/name translation)
 - note: core Internet function, implemented as application-layer protocol
 - complexity at network's "edge"

DNS: services, structure

DNS services:

- hostname-to-IP-address translation
- host aliasing
 - canonical, alias names
- mail server aliasing
- load distribution
 - replicated Web servers: many IP addresses correspond to one name

Q: Why not centralize DNS?

- single point of failure
- traffic volume
- distant centralized database
- maintenance

A: doesn't scale!

- Comcast DNS servers alone: 600B DNS queries/day
- Akamai DNS servers alone:2.2T DNS queries/day

Thinking about the DNS

humongous distributed database:

~ billion records, each simple

handles many trillions of queries/day:

- many more reads than writes
- performance matters: almost every Internet transaction interacts with DNS - msecs count!

organizationally, physically decentralized:

 millions of different organizations responsible for their records

"bulletproof": reliability, security

DNS: a distributed, hierarchical database

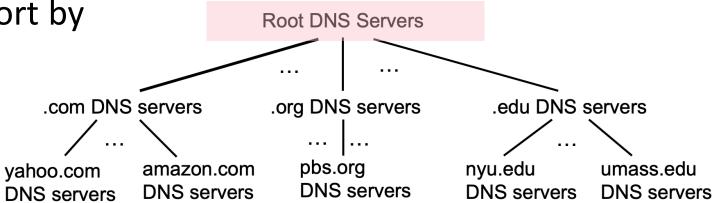

Client wants IP address for www.amazon.com; 1st approximation:

- client queries root server to find .com DNS server
- client queries .com DNS server to get amazon.com DNS server
- client queries amazon.com DNS server to get IP address for www.amazon.com

DNS: root name servers

 official, contact-of-last-resort by name servers that can not resolve name

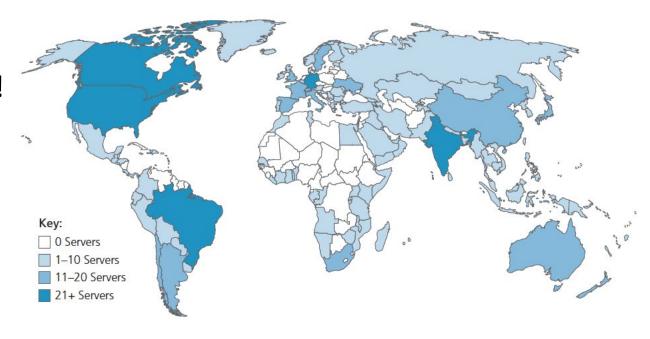

DNS: root name servers

- official, contact-of-last-resort by name servers that can not resolve name
- incredibly important Internet function
 - Internet couldn't function without it!
 - DNSSEC provides security (authentication, message integrity)
- ICANN (Internet Corporation for Assigned Names and Numbers) manages root DNS domain

13 logical root name "servers" worldwide each "server" replicated many times (~200 servers in US)

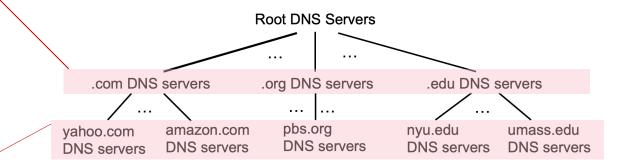

Top-Level Domain, and authoritative servers

Top-Level Domain (TLD) servers:

- responsible for .com, .org, .net, .edu, .aero, .jobs, .museums, and all top-level country domains, e.g.: .cn, .uk, .fr, .ca, .jp
- Network Solutions: authoritative registry for .com, .net TLD
- Educause: .edu TLD

authoritative DNS servers:

- organization's own DNS server(s), providing authoritative hostname to IP mappings for organization's named hosts
- can be maintained by organization or service provider

Local DNS name servers

- when host makes DNS query, it is sent to its local DNS server
 - Local DNS server returns reply, answering:
 - from its local cache of recent name-to-address translation pairs (possibly out of date!)
 - forwarding request into DNS hierarchy for resolution
 - each ISP has local DNS name server; to find yours:
 - MacOS: % scutil --dns
 - Windows: >ipconfig /all
- local DNS server doesn't strictly belong to hierarchy

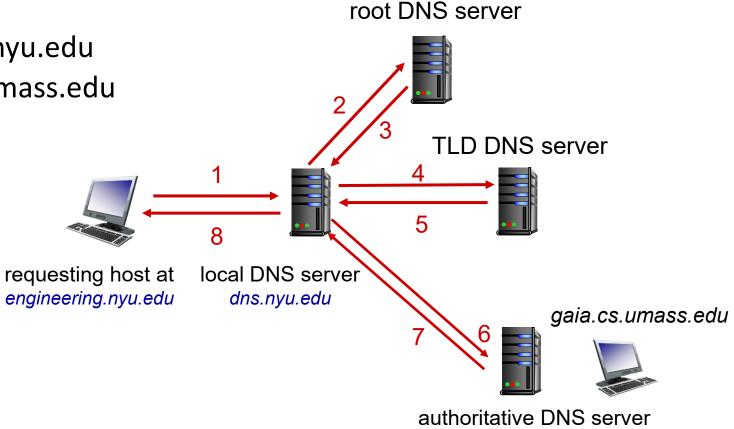

DNS name resolution: iterated query

Example: host at engineering.nyu.edu wants IP address for gaia.cs.umass.edu

Iterated query:

- contacted server replies with name of server to contact
- "I don't know this name, but ask this server"

authoritative DNS server dns.cs.umass.edu

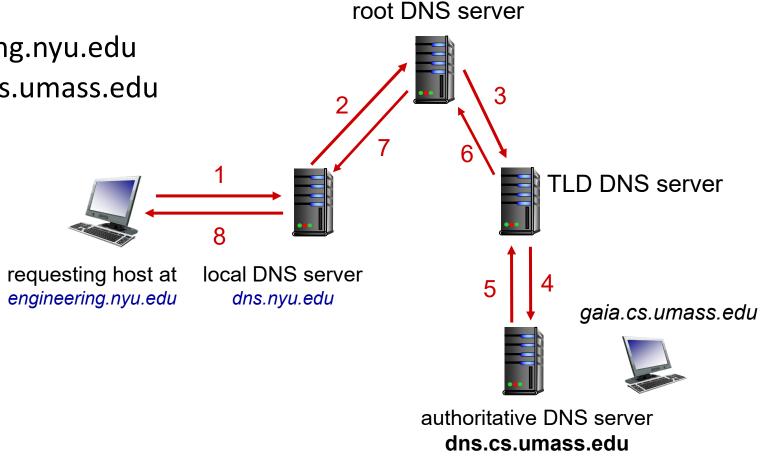

DNS name resolution: recursive query

Example: host at engineering.nyu.edu wants IP address for gaia.cs.umass.edu

Recursive query:

- puts burden of name resolution on contacted name server
- heavy load at upper levels of hierarchy?

Caching DNS Information

- once (any) name server learns mapping, it caches mapping, and immediately returns a cached mapping in response to a query
 - caching improves response time
 - cache entries timeout (disappear) after some time (TTL)
 - TLD servers typically cached in local name servers
- cached entries may be out-of-date
 - if named host changes IP address, may not be known Internetwide until all TTLs expire!
 - best-effort name-to-address translation!

DNS security

DDoS attacks

- bombard root servers with traffic
 - not successful to date
 - traffic filtering
 - local DNS servers cache IPs of TLD servers, allowing root server bypass
- bombard TLD servers
 - potentially more dangerous

Spoofing attacks

- intercept DNS queries, returning bogus replies
 - DNS cache poisoning
 - RFC 4033: DNSSEC authentication services
